Welcome to GNSS-SDR!

GNSS-SDR is an open-source [GNSS software receiver](#) freely available to the research community. This project provides a common framework for GNSS signal processing which can operate in a variety of computer platforms. This tool is intended to foster collaboration, increase awareness, and reduce development costs in the field of GNSS receiver design and customized use of GNSS signals.

For details about GNSS-SDR and using it, please see the [main project page](#) or browse [the source code at GitHub](#). You could be also interested in [subscribing to the mailing list](#).

1.2 Overview

GNSS-SDR provides an interface to different suitable RF front-ends and implements all the receiver chain up to the navigation solution. Its design allows any kind of customization, including interchangeability of signal sources, signal processing algorithms, interoperability with other systems, output formats, and offers interfaces to all the intermediate signals, parameters and variables. The goal is to write efficient and truly reusable code, easy to read and maintain, with fewer bugs, and producing highly optimized executables in a variety of hardware platforms and operating systems. In that sense, the challenge consists of defining a gentle balance within level of abstraction and performance. GNSS-SDR runs in a personal computer and provides interfaces through USB and Ethernet buses to a variety of either commercially available or custom-made RF front-ends, adapting the processing algorithms to different sampling frequencies, intermediate frequencies and sample resolutions. This makes possible rapid prototyping of specific receivers intended, for instance, to geodetic applications, observation of the ionospheric impact on navigation signals, GNSS reflectometry, signal quality monitoring, or carrier-phase based navigation techniques.

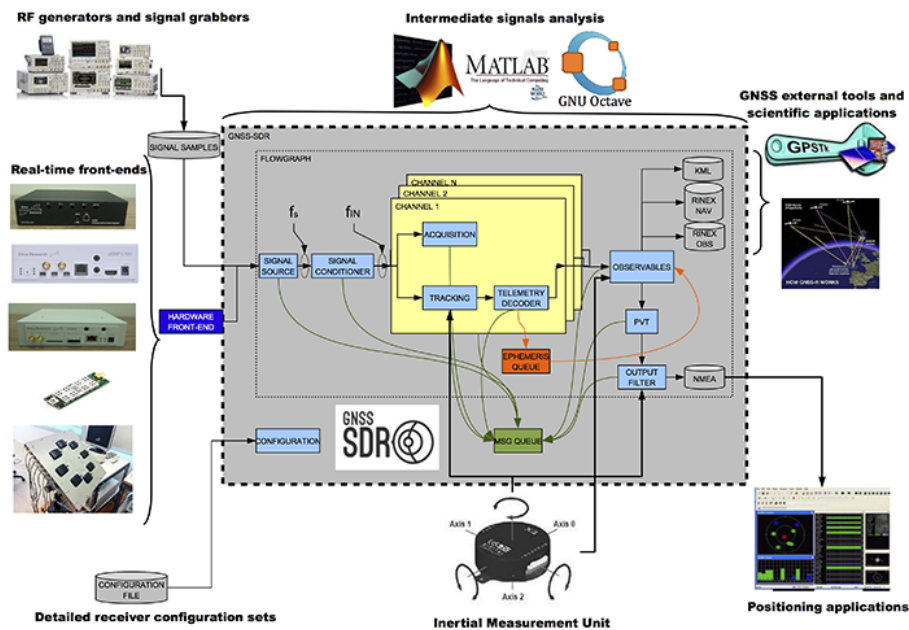

Figure 1.2 Overview

As signal inputs, it accepts:

- Raw data file captured with a data grabber (digitized at some intermediate frequency or directly at baseband).
- Any suitable RF configuration that can be driven by the Universal Software Radio Peripheral Hardware Driver (UHD). This includes all current and future Ettus Research products. The USRP1 + DBSRX 2.2 daughterboard is an example of working configuration for GPS L1 C/A and Galileo E1B and E1C signals.

- Experimentally, with some [USB DVB-T dongles based on the Realtek RTL2832U chipset](#).
- For mathematical representations of the targeted signals, check out the [Signal model](#) page.

As outputs, it provides:

- Dump of intermediate signals (configurable by the user)
- The processing is logged at a system temporary folder (usually, `/tmp`)
- Observables in form of RINEX file (experimental)
- Navigation message data in form of RINEX file
- Position, Velocity and Time solution in KML format and NMEA

1.3 Building GNSS-SDR

In principle, GNSS-SDR can be built in any Unix-like system. In practice, it depends on being able to install all the required dependencies. See the [building guide](#) page for details about the project's dependencies and build process. Mainly, it consists on installing [GNU Radio](#) plus some few more libraries:

- [Armadillo](#), a C++ linear algebra library,
- [Boost](#), a set of free peer-reviewed portable C++ source libraries,
- [Gflags](#), a library that implements commandline flags processing,
- [Glog](#), a library that implements application-level logging,
- [Googletest](#), Google's framework for writing C++ tests,
- [Mako](#), a template library written in Python,
- [Matio](#), a MATLAB MAT File I/O Library,
- [Protocol Buffers](#), a language-neutral, platform-neutral extensible mechanism for serializing structured data,
- [PugiXML](#), a light-weight, simple and fast XML parser for C++ with XPath support,
- [Volk](#), a Vector-Optimized Library of Kernels which provides an abstraction of optimized math routines targeting several SIMD processors,

and, optionally,

- GNU Radio modules for hardware interface ([gr-uhd](#), [gr-osmosdr](#), [gr-iio](#)),
- [Benchmark](#), a library to benchmark code snippets,
- [Gperftools](#), which provides fast, multi-threaded `malloc()` and performance analysis tools.

After all dependencies are installed, clone the GNSS-SDR repository:

```
$ git clone https://github.com/gnss-sdr/gnss-sdr
```

This will create a folder named `gnss-sdr` with the following structure:

```
|-gnss-sdr
|---cmake          <- CMake-related files
|---conf           <- Configuration files. Each file represents one receiver.
|---docs           <- Contains documentation-related files
|---install        <- Executables
|---src            <- Source code folder
|-----algorithms
|-----PVT
|-----acquisition
|-----channel
|-----conditioner
|-----data_type_adapter
|-----input_filter
|-----libs
|-----observables
|-----resampler

|-----core
|-----interfaces
|-----libs
|-----receiver
|-----system_parameters
|-----main
|---tests
|---utils          <- some utilities (e.g. Matlab scripts)
```

You are now ready to build GNSS-SDR by using **CMake** as building tool:

```
$ cd gnss-sdr && mkdir build && cd build
$ cmake ..
$ make
```

If everything goes well, three new executables will be created at `gnss-sdr/install`, namely `gnss-sdr`, `volk_gnssdr_profile` and `run_tests`. You can run them from that folder, but if you prefer to install `gnss-sdr` on your system and have it available anywhere else, do:

```
$ sudo make install
```

This will make a copy of the `conf/` folder into `/usr/local/share/gnss-sdr/conf` for your reference. We suggest to create a working directory at your preferred location and store your own configuration and data files there.

You can create the documentation by doing:

```
$ make doc
```

from the building folder. In both cases, **Doxygen** will generate HTML documentation that can be retrieved pointing your browser of preference to `gnss-sdr/docs/html/index.html`.

There are two more extra targets available. In the building folder:

```
$ make doc-clean
```

will remove the content of previously-generated documentation and, if a LaTeX installation is detected in your system,

```
$ make pdfmanual
```

will create a PDF manual at `gnss-sdr/docs/GNSS-SDR_manual.pdf`. Please note that the PDF generation requires some fonts to be installed on the host system. In Ubuntu, those fonts do not come by default. You can install them by doing:

```
$ sudo apt install texlive-fonts-recommended
```

and then run `cmake ../` and `make pdfmanual` again.

1.3.1 Debug and Release builds

By default, CMake will build the Release version, meaning that the compiler will generate a faster, optimized executable. This is the recommended build type when using a RF front-end and you need to attain real time. If working with a file (and thus without real-time constraints), you may want to obtain more information about the internals of the receiver, as well as more fine-grained logging. This can be done by building the Debug version, by doing:

```
$ cd gnss-sdr && mkdir build-debug && cd build-debug
$ cmake -DCMAKE_BUILD_TYPE=Debug ..
$ make
```

1.3.2 Updating GNSS-SDR

If you checked out GNSS-SDR some days ago, it is possible that some developer had updated files at the Git repository. You can update your local copy by doing:

```
$ git checkout next
$ git pull https://github.com/gnss-sdr/gnss-sdr next
```

Before rebuilding the source code, it is safe (and recommended) to remove the remainders of old builds:

```
$ cd <building folder>
$ sudo make uninstall ; if you installed it before
$ rm -rf *
```

You can also check [The Git Book](#) for more information about Git usage.

1.4 Using GNSS-SDR

With GNSS-SDR, you can define your own receiver, work with captured raw data or from a RF front-end, dump into files intermediate signals, or tune every single algorithm used in the [Signal Processing plane](#). All the configuration is done in a single file. Those configuration files reside at the `gnss-sdr/conf` folder. By default, the executable `gnss-sdr` will read the configuration available at `gnss-sdr/conf/gnss-sdr.conf`. You can edit that file to fit your needs, or even better, define a new `my_receiver.conf` file with your own configuration. This new receiver can be done by invoking `gnss-sdr` with the `-config_file` flag pointing to your configuration file:

```
$ gnss-sdr --config_file=../conf/my_receiver.conf
```

You can see a guide of available implementations at [the online documentation](#). That folder contains other working examples as well. If you have a working configuration and want to share it with others, please email it to the [GNSS-SDR developers mailing list](#) and we will be happy to upload it to the server.

You can use a single configuration file for processing different data files, specifying the file to be processed with the `-signal_source` flag:

```
$ gnss-sdr --config_file=../conf/my_receiver.conf --signal_source=../my_captured_data.dat
```

This will override the `SignalSource.filename` specified in the configuration file.

You can get a complete list of available commandline flags by doing:

```
$ gnss-sdr --help
```

1.5 Control plane

GNSS-SDR's main method initializes the logging library, processes the command line flags, if any, provided by the user and instantiates a [ControlThread](#) object. Its constructor reads the configuration file, creates a control queue and creates a flowgraph according to the configuration. Then, the program's main method calls the `run()` method of the instantiated object, an action that connects the flowgraph and starts running it. After that, and until a stop message is received, it reads control messages sent by the receiver's modules through a safe-thread queue and processes them. Finally, when a stop message is received, the main method executes the destructor of the [ControlThread](#) object, which deallocates memory, does other cleanup and exits the program.

The [GNSSFlowgraph](#) class is responsible for preparing the graph of blocks according to the configuration, running it, modifying it during run-time and stopping it. Blocks are identified by its role. This class knows which roles it has to instantiate and how to connect them. It relies on the configuration to get the correct instances of the roles it needs and then it applies the connections between GNU Radio blocks to make the graph ready to be started. The complexity related to managing the blocks and the data stream is handled by GNU Radio's `gr::top_block` class. [GNSSFlowgraph](#) wraps the `gr::top_block` instance so we can take advantage of the [GNSS block factory](#), the configuration system and the processing blocks. This class is also responsible for applying changes to the configuration of the flowgraph during run-time, dynamically reconfiguring channels: it selects the strategy for selecting satellites. This can range from a sequential search over all the satellites' ID to smarter approaches that determine what are the satellites most likely in-view based on rough estimations of the receiver position in order to avoid searching satellites in the other side of the Earth.

The Control Plane is in charge of creating a flowgraph according to the configuration and then managing the modules. Configuration allows users to define in an easy way their own custom receiver by specifying the flowgraph (type of signal source, number of channels, algorithms to be used for each channel and each module, strategies for satellite selection, type of output format, etc.). Since it is difficult to foresee what future module implementations will be needed in terms of configuration, we used a very simple approach that can be extended without a major impact in the code. This can be achieved by simply mapping the names of the variables in the modules with the names of the parameters in the configuration.

1.5.1 Configuration

Properties are passed around within the program using the [ConfigurationInterface](#) class. There are two implementations of this interface: [FileConfiguration](#) and [InMemoryConfiguration](#). [FileConfiguration](#) reads the properties (pairs of property name and value) from a file and stores them internally. [InMemoryConfiguration](#) does not read from a file; it remains empty after instantiation and property values and names are set using the `set` property method. [FileConfiguration](#) is intended to be used in the actual GNSS-SDR application whereas [InMemoryConfiguration](#) is intended to be used in tests to avoid file-dependency in the file system. Classes that need to read configuration parameters will receive instances of [ConfigurationInterface](#) from where they will fetch the values. For instance, parameters related to `SignalSource` should look like this:

```
SignalSource.parameter1=value1
SignalSource.parameter2=value2
```

The name of these parameters can be anything but one reserved word: `implementation`. This parameter indicates in its value the name of the class that has to be instantiated by the factory for that role. For instance, if our signal source is providing data already at baseband and thus we want to use the implementation [Pass_Through](#) for module [SignalConditioner](#), the corresponding line in the configuration file would be

```
SignalConditioner.implementation=Pass_Through
```

Since the configuration is just a set of property names and values without any meaning or syntax, the system is very versatile and easily extendable. Adding new properties to the system only implies modifications in the classes that will make use of these properties. In addition, the configuration files are not checked against any strict syntax so it is always in a correct status (as long as it contains pairs of property names and values in [INI format](#)).

1.5.2 GNSS block factory

Hence, the application defines a simple accessor class to fetch the configuration pairs of values and passes them to a factory class called [GNSSBlockFactory](#). This factory decides, according to the configuration, which class needs to be instantiated and which parameters should be passed to the constructor. Hence, the factory encapsulates the complexity of blocks' instantiation. With that approach, adding a new block that requires new parameters will be as simple as adding the block class and modifying the factory to be able to instantiate it. This loose coupling between the blocks' implementations and the syntax of the configuration enables extending the application capacities in a high degree. It also allows to produce fully customized receivers, for instance a testbed for acquisition algorithms, and to place observers at any point of the receiver chain.

1.6 Signal Processing plane

GNU Radio's class `gr::basic_block` is the abstract base class for all signal processing blocks, a bare abstraction of an entity that has a name and a set of inputs and outputs. It is never instantiated directly; rather, this is the abstract parent class of both `gr::hier_block2`, which is a recursive container that adds or removes processing or hierarchical blocks to the internal graph, and `gr::block`, which is the abstract base class for all the processing blocks.

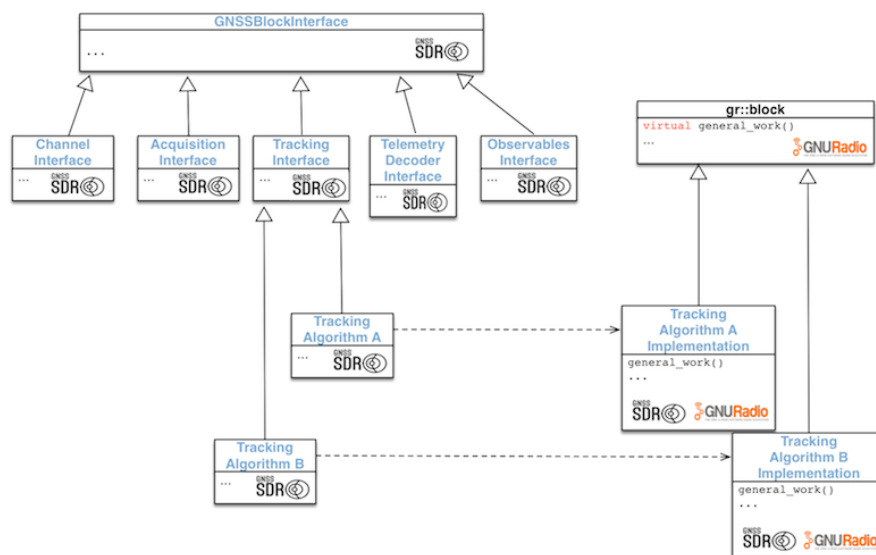

Figure 1.3 Class hierarchy of signal processing blocks

A signal processing flow is constructed by creating a tree of hierarchical blocks, which at any level may also contain terminal nodes that actually implement signal processing functions.

Class `gr::top_block` is the top-level hierarchical block representing a flowgraph. It defines GNU Radio run-time functions used during the execution of the program: `run()`, `start()`, `stop()`, `wait()`, etc. A subclass called [GNSSBlockInterface](#) is the common interface for all the GNSS-SDR modules. It defines pure virtual methods, that are required to be implemented by a derived class.

Subclassing [GNSSBlockInterface](#), we defined interfaces for the GNSS receiver blocks depicted in the figure above. This hierarchy provides the definition of different algorithms and different implementations, which will be instantiated according to the configuration. This strategy allows multiple implementations sharing a common interface, achieving the objective of decoupling interfaces from implementations: it defines a family of algorithms, encapsulates each one, and makes them interchangeable. Hence, we let the algorithm vary independently from the program that uses it.

1.6.1 Signal Source

The input of a software receiver are the raw bits that come out from the front-end's analog-to-digital converter (ADC). Those bits can be read from a file stored in the hard disk or directly in real-time from a hardware device through USB or Ethernet buses.

The Signal Source module is in charge of implementing the hardware driver, that is, the portion of the code that communicates with the RF front-end and receives the samples coming from the ADC. This communication is usually performed through USB or Ethernet buses. Since real-time processing requires a highly optimized implementation of the whole receiver, this module also allows to read samples from a file stored in a hard disk, and thus processing without time constraints. Relevant parameters of those samples are the intermediate frequency (or baseband I&Q components), the sampling rate and number of bits per sample, that must be specified by the user in the configuration file.

This module also performs bit-depth adaptation, since most of the existing RF front-ends provide samples quantized with 2 or 3 bits, while operations inside the processor are performed on 32- or 64-bit words, depending on its architecture. Although there are implementations of the most intensive computational processes (mainly correlation) that take advantage of specific data types and architectures for the sake of efficiency, the approach is processor-specific and hardly portable. We suggest to keep signal samples in standard data types and letting the compiler select the best library version (implemented using SIMD or any other processor-specific technology) of the required routines for a given processor.

Example: [FileSignalSource](#)

The user can configure the receiver for reading from a file, setting in the configuration file the data file location, sample format, and the sampling frequency and intermediate frequency at what the signal was originally captured.

```
##### SIGNAL_SOURCE CONFIG #####
SignalSource.implementation=File_Signal_Source
SignalSource.filename=/home/user/gnss-sdr/data/my_capture.dat
SignalSource.item_type=gr_complex
SignalSource.sampling_frequency=4000000 ; Sampling frequency in [Hz]
SignalSource.freq=1575420000 ; RF front-end center frequency in [Hz]
```

Example: [UhdSignalSource](#)

The user may prefer to use a UHD-compatible RF front-end and try real-time processing. For instance, for a USRP1 + DBSRX daughterboard, use:

```
##### SIGNAL_SOURCE CONFIG #####
SignalSource.implementation=UHD_Signal_Source
SignalSource.item_type=gr_complex
SignalSource.sampling_frequency=4000000 ; Sampling frequency in [Hz]
SignalSource.freq=1575420000 ; RF front-end center frequency in [Hz]
SignalSource.gain=60 ; Front-end gain in dB
SignalSource.subdevice=B:0 ; UHD subdevice specification (for USRP1 use A:0 or B:0)
```

Other examples are available at `gnss-sdr/conf`.

1.6.2 Signal Conditioner

The signal conditioner is in charge of resampling the signal and delivering a reference sample rate to the downstream processing blocks, acting as a facade between the signal source and the synchronization channels, providing a simplified interface to the input signal. In case of multiband front-ends, this module would be in charge of providing a separated data stream for each band.

1.6.3 Channel

A channel encapsulates all signal processing devoted to a single satellite. Thus, it is a large composite object which encapsulates the [Acquisition](#), [Tracking](#) and [Decoding of the navigation message](#) modules. As a composite object, it can be treated as a single entity, meaning that it can be easily replicated. Since the number of channels is selectable by the user in the configuration file, this approach helps improving the scalability and maintainability of the receiver.

This module is also in charge of managing the interplay between acquisition and tracking. Acquisition can be initialized in several ways, depending on the prior information available (called cold start when the receiver has no information about its position nor the satellites almanac; warm start when a rough location and the approximate time of day are available, and the receiver has a recently recorded almanac broadcast; or hot start when the receiver was tracking a satellite and the signal line of sight broke for a short period of time, but the ephemeris and almanac data is still valid, or this information is provided by other means), and an acquisition process can finish deciding that the satellite is not present, that longer integration is needed in order to confirm the presence of the satellite, or declaring the satellite present. In the latter case, acquisition process should stop and trigger the tracking module with coarse estimations of the synchronization parameters.

The abstract class [ChannelInterface](#) represents an interface to a channel GNSS block. Check [Channel](#) for an actual implementation.

1.6.3.1 Acquisition

The first task of a GNSS receiver is to detect the presence or absence of in-view satellites. This is done by the acquisition system process, which also provides a coarse estimation of two signal parameters: the frequency shift with respect to the nominal IF frequency, and a delay term which allows the receiver to create a local code aligned with the incoming code. [AcquisitionInterface](#) is the common interface for all the acquisition algorithms and their corresponding implementations. Algorithms' interface, that may vary depending on the use of information external to the receiver, such as in Assisted GNSS, is defined in classes referred to as *adapters*. These adapters wrap the GNU Radio blocks interface into a compatible interface expected by [AcquisitionInterface](#). This allows the use of existing GNU Radio blocks derived from `gr::block`, and ensures that newly developed implementations will also be reusable in other GNU Radio-based applications. Moreover, it adds still another layer of abstraction, since each given acquisition algorithm can have different implementations (for instance using different numerical libraries). In such a way, implementations can be continuously improved without having any impact neither on the algorithm interface nor the general acquisition interface.

Check [GpsL1CaPcpsAcquisition](#) and [GalileoE1PcpsAmbiguousAcquisition](#) for examples of adapters from a Parallel Code Phase Search (PCPS) acquisition block, and `pcps_acquisition_cc` for an example of a block implementation. The source code of all the available acquisition algorithms is located at:

```
| -gnss-sdr
| ---src
| ----algorithms
| -----acquisition
| -----adapters          <- Adapters of the processing blocks to an AcquisitionInterface
| -----gnuradio_blocks   <- Signal processing blocks implementation
```

The user can select a given implementation for the algorithm to be used in each receiver channel, as well as their parameters, in the configuration file:

```
##### ACQUISITION GLOBAL CONFIG #####

;#implementation: Acquisition algorithm selection for this channel:
Acquisition_1C.implementation=GPS_L1_CA_PCPS_Acquisition
;#dump: Enable or disable the acquisition internal data file logging [true] or [false]
Acquisition_1C.dump=false
;#filename: Log path and filename
Acquisition_1C.dump_filename=./acq_dump.dat
```

```
;#item_type: Type and resolution for each of the signal samples. Use only gr_complex in this version.
Acquisition_1C.item_type=gr_complex
;#coherent_integration_time_ms: Signal block duration for the acquisition signal detection [ms]
Acquisition_1C.coherent_integration_time_ms=1
;#threshold: Acquisition threshold
Acquisition_1C.threshold=2.5
;#pfa: Acquisition false alarm probability. This option overrides the threshold option.
Acquisition_1C.pfa=0.0001
;#doppler_max: Maximum expected Doppler shift [Hz]
Acquisition_1C.doppler_max=5000
;#doppler_step: Doppler step in the grid search [Hz]
Acquisition_1C.doppler_step=250
```

1.6.3.2 Tracking

When a satellite is declared present, the parameters estimated by the acquisition module are then fed to the receiver tracking module, which represents the second stage of the signal processing unit, aiming to perform a local search for accurate estimates of code delay and carrier phase, and following their eventual variations.

Again, a class hierarchy consisting of a [TrackingInterface](#) class and subclasses implementing algorithms provides a way of testing different approaches, with full access to their parameters. Check [GpsL1CaDlIPllTracking](#) or [GalileoE1DlIPllVemlTracking](#) for examples of adapters, and [Gps_L1_Ca_Dll_Pll_Tracking_cc](#) for an example of a signal processing block implementation. There are also available some useful classes and functions for signal tracking; take a look at Correlator, [lock_detectors.h](#), [tracking_discriminators.h](#) or [tracking_2nd_DLL_filter.h](#).

The source code of all the available tracking algorithms is located at:

```
| -gnss-sdr
| ---src
| ----algorithms
| -----tracking
| -----adapters          <- Adapters of the processing blocks to a TrackingInterface
| -----gnuradio_blocks    <- Signal processing blocks implementation
| -----libs               <- libraries of tracking objects (e.g. correlators, discriminators, and so on)
```

The user can select a given implementation for the algorithm to be used in all the tracking blocks, as well as its parameters, in the configuration file:

```
##### TRACKING GLOBAL CONFIG #####

;#implementation: Selected tracking algorithm
Tracking_1C.implementation=GPS_L1_CA_DLL_PLL_Tracking
;#item_type: Type and resolution for each of the signal samples.
Tracking_1C.item_type=gr_complex

;#dump: Enable or disable the Tracking internal binary data file logging [true] or [false]
Tracking_1C.dump=false

;#dump_filename: Log path and filename. Notice that the tracking channel will add "x.dat" where x is the channel
Tracking_1C.dump_filename=./tracking_ch_

;#pll_bw_hz: PLL loop filter bandwidth [Hz]
Tracking_1C.pll_bw_hz=50.0;

;#dll_bw_hz: DLL loop filter bandwidth [Hz]
Tracking_1C.dll_bw_hz=2.0;

;#fll_bw_hz: FLL loop filter bandwidth [Hz]
Tracking_1C.fll_bw_hz=10.0;

Tracking_1C.pll_filter_order=3 ; PLL loop filter order [2] or [3]
Tracking_1C.dll_filter_order=2 ; DLL loop filter order [1], [2] or [3]

;#early_late_space_chips: correlator early-late space [chips].
Tracking_1C.early_late_space_chips=0.5;
```

1.6.3.3 Decoding of the navigation message

Most of GNSS signal links are modulated by a navigation message containing the time the message was transmitted, orbital parameters of satellites (also known as ephemeris) and an almanac (information about the general system health, rough orbits of all satellites in the network as well as data related to error correction). Navigation data bits are structured in words, pages, subframes, frames and superframes. Sometimes, bits corresponding to a single parameter are spread over different words, and values extracted from different frames are required for proper decoding. Some words are for synchronization purposes, others for error control and others contain actual information. There are also error control mechanisms, from parity checks to forward error correction (FEC) encoding and interleaving, depending on the system.

The common interface is [TelemetryDecoderInterface](#). Check [GpsL1CaTelemetryDecoder](#) for an example of the GPS L1 NAV message decoding adapter, and `gps_l1_ca_telemetry_decoder_cc` for an actual implementation of a signal processing block. Configuration example:

```
;##### TELEMETRY DECODER CONFIG #####
TelemetryDecoder_1C.implementation=Gps_L1_CA_Telemetry_Decoder
TelemetryDecoder_1C.dump=false
```

See the [Reference Documents](#) for more information about the signal format.

1.6.4 Observables

GNSS systems provide different kinds of observations. The most commonly used are the code observations, also called pseudoranges. The *pseudo* comes from the fact that on the receiver side the clock error is unknown and thus the measurement is not a pure range observation. High accuracy applications also use the carrier phase observations, which are based on measuring the difference between the carrier phase transmitted by the GNSS satellites and the phase of the carrier generated in the receiver. Both observables are computed from the outputs of the tracking module and the decoding of the navigation message. This module collects all the data provided by every tracked channel, aligns all received data into a coherent set, and computes the observables.

The common interface is [ObservablesInterface](#).

Configuration example:

```
;##### OBSERVABLES CONFIG #####
Observables.implementation=Hybrid_Observables

;#dump: Enable or disable the Observables internal binary data file logging [true] or [false]
Observables.dump=false

;#dump_filename: Log path and filename.
Observables.dump_filename=./observables.dat
```

1.6.5 Computation of Position, Velocity and Time

Although data processing for obtaining high-accuracy PVT solutions is out of the scope of GNSS-SDR, we provide a module that can compute a simple least square solution and leaves room for more sophisticated positioning methods. The integration with libraries and software tools that are able to deal with multi-constellation data such as [GNSSTk](#) or [gLAB](#) appears as a viable solution for high performance, completely customizable GNSS receivers.

The common interface is [PvtInterface](#). For instance, in order to use the implementation `RTKLIB_PVT`, add to the configuration file:

```

;##### PVT CONFIG #####
PVT.implementation=RTKLIB_PVT

;#nmea_dump_filename: NMEA log path and filename
PVT.nmea_dump_filename=./gnss_sdr_pvt.nmea;

;#flag_nmea_tty_port: Enable or disable the NMEA log to a serial TTY port (Can be used with real hardware or v
PVT.flag_nmea_tty_port=true;

;#nmea_dump_devname: serial device descriptor for NMEA logging
PVT.nmea_dump_devname=/dev/pts/4

;#dump: Enable or disable the PVT internal binary data file logging [true] or [false]
PVT.dump=false

```

This implementation allows tuning of the following parameters:

```

PVT.implementation=RTKLIB_PVT
PVT.positioning_mode=Single      ; options: Single, Static, Kinematic, PPP_Static, PPP_Kinematic
PVT.iono_model=Broadcast        ; options: OFF, Broadcast
PVT.trop_model=Saastamoinen     ; options: OFF, Saastamoinen
PVT.rinex_version=2             ; options: 2 or 3
PVT.output_rate_ms=100         ; Period in [ms] between two PVT outputs
PVT.display_rate_ms=500        ; Position console print (std::out) interval [ms].
PVT.nmea_dump_filename=./gnss_sdr_pvt.nmea ; NMEA log path and filename
PVT.flag_nmea_tty_port=false    ; Enables the NMEA log to a serial TTY port
PVT.nmea_dump_devname=/dev/pts/4 ; serial device descriptor for NMEA logging
PVT.flag_rtcn_server=true       ; Enables or disables a TCP/IP server dispatching RTCM messages
PVT.flag_rtcn_tty_port=false    ; Enables the RTCM log to a serial TTY port
PVT.rtcn_dump_devname=/dev/pts/1 ; serial device descriptor for RTCM logging
PVT.rtcn_tcp_port=2101

1.7 About the software license

GNSS-SDR is released under the [General Public License \(GPL\) v3](#), thus securing practical usability, inspection, and continuous improvement by the research community, allowing the discussion based on tangible code and the analysis of results obtained with real signals. The GPL implies that:

- Copies may be distributed free of charge or for money, but the source code has to be shipped or provided free of charge (or at cost price) on demand. The receiver of the source code has the same rights meaning he can share copies free of charge or resell.
- The licensed material may be analyzed or modified.
- Modified material may be distributed under the same licensing terms but **do not** have to be distributed.

That means that modifications only have to be made available to the public if distribution happens. So it is perfectly fine to take the GNSS-SDR source code, modify it heavily and use it in a not distributed application / library. This is how companies like Google can run their own patched versions of Linux for example.

But what this also means is that non-GPL code cannot use GPL code. This means that you cannot modify / use GNSS-SDR, blend it with non-GPL code, and make money with the resulting software. You cannot distribute the resulting software under a non-disclosure agreement or contract. Distributors under the GPL also grant a license for any of their patents practiced by the software, to practice those patents in GPL software. You can sell a device that runs with GNSS-SDR, but if you distribute the code, it has to remain under GPL.

1.9 Ok, now what?

In order to start using GNSS-SDR, you may want to populate `gnss-sdr/data` folder (or anywhere else on your system) with raw data files. By "raw data" we mean the output of a Radio Frequency front-end's Analog-to-Digital converter. GNSS-SDR needs signal samples already in baseband or in passband, at a suitable intermediate frequency (on the order of MHz). Prepare your configuration file, and then you are ready for going to the `gnss-sdr/install` folder, running `./gnss-sdr`, and see how the file is processed. Please ask the Developer Team for a signal sample if you need one, and they will do their best ;-)

Another interesting option is working in real-time with a RF front-end. We provide drivers for UHD-compatible hardware (see [Signal Source](#)) and for some DVB-T USB dongles. Start with a low number of channels and then increase it in order to test how many channels your processor can handle in real-time.

You can find more information at the [GNSS-SDR Documentation page](#) or directly asking to the [GNSS-SDR Developers mailing list](#).

You are also very welcome to contribute to the project, there are many ways to [participate in GNSS-SDR](#). If you need some special feature not yet implemented, the Developer Team would love to be hired for developing it. Please do not hesitate to [contact them](#).

Enjoy GNSS-SDR!

The Developer Team.

2.2 Other Standards

2.2.1 RINEX

The final output of a navigation receiver is usually its position, speed or other related physical quantities. However, the calculation of those quantities are based on a series of measurements from one or more satellite constellations. Although receivers calculate positions in real time, in many cases it is interesting to store intermediate measures for later post-processing. RINEX is the standard format that allows the management and disposal of the measures generated by a receiver, as well as their off-line processing by a multitude of applications.

- The most common version at present is **RINEX: The Receiver Independent Exchange Format Version 2.12**, which enables storage of measurements from pseudorange, carrier-phase and Doppler systems for GPS, GLONASS, Galileo along with data from EGNOS and WAAS satellite based augmentation systems (SBAS).
- The most recent version is **RINEX: The Receiver Independent Exchange Format Version 3.03** published in July, 2015. It includes Galileo and improves the handling of multi-constellation data files.
- There is also available the **RINEX Extensions to Handle Clock Information**, published in September, 2010.

2.2.2 NMEA

The [National Marine Electronics Association](#) released the NMEA 0183 Interface Standard, which defines electrical signal requirements, data transmission protocol and time, and specific sentence formats for a 4800-baud serial data bus. The standard is [available for purchase](#).

2.2.3 KML

KML is an XML language focused on geographic visualization, including annotation of maps and images. Geographic visualization includes not only the presentation of graphical data on the globe, but also the control of the user's navigation in the sense of where to go and where to look. Google submitted KML (formerly Keyhole Markup Language) to the Open Geospatial Consortium (OGC) to be evolved within the OGC consensus process with the following goal: KML Version 2.2 has been adopted as an OGC implementation standard.

2.2.4 C++ Standards

The C++ programming language is standardized by the International Organization for Standardization (ISO), with the latest standard version ratified and published by ISO in December 2017 as ISO/IEC 14882:2017 (informally known as C++17). The list of supported C++ standards (the highest available is automatically selected by the CMake script):

2.2.5 Positioning protocols in wireless communication networks

Cellular industry location standards first appeared in the late 1990s, with the [3rd generation partnership project \(3GPP\)](#) radio resource location services protocol (RRLP) technical specification 44.031 positioning protocol for GSM networks. Today, RRLP is the de facto standardized protocol to carry GNSS assistance data to GNSS-enabled mobile devices, and the term "3GPP specification" now covers all GSM (including GPRS and EDGE), W-CDMA and LTE (including LTE-A) specifications. Precisely, the label "LTE-A" is applied to networks compliant with LTE Release 10 and beyond, which fulfill the requirements issued by the [International Telecommunication Union Radiocommunication Sector \(ITU-R\)](https://www.itu.int/en/ITU-R/Pages/default.aspx) in the global standard for international mobile telecommunications (IMT Advanced, also referred to as 4G) access technologies. Control plane protocols: \li Radio Resource LCS Protocol (RRLP): <https://www.3gpp.org/ftp/Specs/html-info/44031.htm> target="_blank">3GPP

Technical Specification 44.031

- LTE Positioning Protocol (LPP): [3GPP Technical Specification 36.355](https://www.3gpp.org/ftp/Specs/html-info/36355.htm). User plane protocols:
 - Open Mobile Alliance (OMA), [Secure User Plane Location Architecture Version 1 \(SUPL 1.0\)](http://member.openmobilealliance.org/ftp/Public_documents/LOC/Permanent_documents/OMA-AD-SUPL-V1_0-20070615-A.zip), June 2007.

LTE Release 9 introduced extension hooks in LPP messages, so that the bodies external to 3GPP could extend the LPP feature set. OMA LPP extensions (LPPe), supported in SUPL 3.0, build on top of the 3GPP LPP reusing its procedures and data types. Check the [OMA Specifications webpage](https://technical.openmobilealliance.org/index.html) for updated information about LPP Extensions (LPPe) Specification.

- The [OMA Mobile Location Protocol \(MLP\) V3.5](http://member.openmobilealliance.org/ftp/Public_documents/loc/Permanent_documents/OMA-TS-MLP-V3_5-20181119-D.zip) is an application-level protocol for getting the position of mobile stations (mobile phones, wireless personal digital assistants, etc.) independent of underlying network technology. The MLP serves as the interface between a Location Server and a Location Services (LCS) Client. This specification defines the core set of operations that a Location Server should be able to perform.

Chapter 3

Signal model

3.1 GNSS signal model

This page describes signals transmitted by GNSS space vehicles. Signal models are mathematical representations of the electromagnetic waves that are exciting the receiver's antenna. The current induced by those waves is then amplified, filtered and downconverted to a suitable frequency (can be at some intermediate frequency or directly to baseband), and then converted to 0s and 1s by the Analog-to-Digital Converter (ADC). That is the job of the Radio Frequency front-end, which at its output delivers a stream of digital samples. Those samples constitute the input of a software receiver, so for GNSS-SDR the signal models described below can be seen as *the rules of the game*.

GNSS' space vehicles are modern versions of lighthouses, but with better visibility. Each satellite is a reference point, and if we know our distance to several reference points, we can compute our location, just as mariners do when they see a couple of lighthouses. For each in-view satellite i of system s , we can write:

$$\rho_i = \sqrt{(x_i^{\text{Tx}} - x)^2 + (y_i^{\text{Tx}} - y)^2 + (z_i^{\text{Tx}} - z)^2} + c\Delta t^{(s)} + \sigma_e, \quad (3.1)$$

where $(x_i^{\text{Tx}}, y_i^{\text{Tx}}, z_i^{\text{Tx}})$ is the satellite's position (known from the navigation message), (x, y, z) the receiver's position, and σ_e gathers other sources of error. Since the receiver needs to estimate its own 3D position (three spatial unknowns) and its clock deviation with respect to the satellites' time basis, at least $3 + N_s$ satellites must be seen by the receiver at the same time, where N_s is the number of different navigation systems available (in-view) at a given time. Each received satellite signal, once synchronized and demodulated at the receiver, defines one equation such as the one defined above, forming a set of nonlinear equations that can be solved algebraically by means of the [Bancroft algorithm](#) or numerically, resorting to multidimensional Newton-Raphson and weighted least square methods. When *a priori* information is added we resort to Bayesian estimation, a problem that can be solved recursively by a Kalman filter or any of its variants. The problem can be further expanded by adding other unknowns (for instance, parameters of ionospheric and tropospheric models), sources of information from other systems, mapping information, and even motion models of the receiver. In the design of multi-constellation GNSS receivers, the vector of unknowns can also include the receiver clock offset with respect to each system in order to take advantage of a higher number of in-view satellites and using them jointly in the navigation solution, therefore increasing accuracy.

The [analytic representation](#) of a signal received from a GNSS satellite can be generically expressed as

$$r(t) = \alpha(t)s_T(t - \tau(t))e^{-j2\pi f_d(t)}e^{j2\pi f_c t} + n(t), \quad (3.2)$$

where $\alpha(t)$ is the amplitude, $s_T(t)$ is the complex baseband transmitted signal, $\tau(t)$ is the time-varying delay, $f_d(t) = f_c\tau(t)$ is the Doppler shift, f_c is the carrier frequency, and $n(t)$ is a noise term. These signals arrive to the Earth's surface at extremely low power (e.g. -158.5 dBW for GPS L1 C/A-code, -157 dBW for Galileo E1), well below the noise floor. In order to estimate its distances to satellites, the receiver must correlate time-aligned replicas of the corresponding pseudorandom code with the incoming signal, in a process called *despreading* that

provides processing gain only to the signal of interest. After a coarse and fine estimation stages of the synchronization parameters (usually known as acquisition and tracking, respectively), signal processing output is in form of *observables*:

i) the pseudorange (code) measurement, equivalent to the difference of the time of reception (expressed in the time frame of the receiver) and the time of transmission (expressed in the time frame of the satellite) of a distinct satellite signal; and optionally

ii) the carrier-phase measurement, actually being a measurement on the beat frequency between the received carrier of the satellite signal and a receiver-generated reference frequency. Carrier phase measurements are ambiguous, in the sense that the integer number of carrier wavelengths between satellite and the receiver's antenna is unknown. Techniques such as **Least-square AMBiguity Decorrelation Approach (LAMBDA)** or Multi Carrier Ambiguity Resolution (MCAR) can be applied to resolve such ambiguity and provide an accurate estimation of the distance between the satellite and the receiver.

Then, depending on the required accuracy, the navigation solution can range from pseudorange-only, computationally low demanding, and limited accuracy least squares methods to sophisticated combinations of code and phase observables at different frequencies for high demanding applications such as surveying, geodesy, and geophysics.

Next sections provide brief descriptions of the space segment of different GNSSs and their broadcast signal structures accessible by civilians.

3.1.1 Global Positioning System (GPS) signal in space

The Global Positioning System (GPS) is a space-based radio-navigation system owned by the United States Government (USG) and operated by the United States Air Force (USAF). GPS provides positioning and timing services to military and civilian users on a continuous, worldwide basis. Two GPS services are provided: the Precise Positioning Service (PPS), available primarily to the military of the United States and its allies, and the Standard Positioning Service (SPS) open to civilian users.

- **GPS L1.** Defined at **Interface Specification IS-GPS-200 Revision M**, this band is centered at $f_{\text{GPS L1}} = 1575.42$ MHz. The complex baseband transmitted signal can be written as

$$s_T^{(\text{GPS L1})}(t) = e_{L1I}(t) + je_{L1Q}(t), \quad (3.3)$$

with

$$e_{L1I}(t) = \sum_{l=-\infty}^{\infty} D_{\text{NAV}}[l]_{204600} \oplus C_{P(Y)}[l]_{L_{P(Y)}} p(t - lT_{c,P(Y)}), \quad (3.4)$$

$$e_{L1Q}(t) = \sum_{l=-\infty}^{\infty} D_{\text{NAV}}[l]_{20460} \oplus C_{C/A}[l]_{1023} p(t - lT_{c,C/A}), \quad (3.5)$$

where \oplus is the exclusive-or operation (modulo-2 addition), $|l|_L$ means l modulo L , $[l]_L$ means the integer part of $\frac{l}{L}$, D_{NAV} is the GPS navigation message bit sequence, transmitted at 50 bps, $T_{c,P(Y)} = \frac{1}{10.23} \mu\text{s}$, $T_{c,C/A} = \frac{1}{1.023} \mu\text{s}$, $L_{P(Y)} = 6.1871 \cdot 10^{12}$, and $p(t)$ is a rectangular pulse of a chip-period duration centered at $t = 0$ and filtered at the transmitter. According to the chip rate, the binary phase-shift keying modulations in the equations above are denoted as BPSK(10) and BPSK(1), respectively. The precision P codes (named Y codes whenever the anti-spoofing mode is activated, encrypting the code and thus denying non-U.S. military users) are sequences of 7 days in length. Regarding the modernization plans for GPS, it is worthwhile to mention that there is a new civilian-use signal planned, called L1C and defined at **Interface Specification IS-GPS-800 Revision H**, to be broadcast on the same L1 frequency that currently contains the C/A signal. The L1C is available with first Block III launch. The implementation provides C/A code to ensure backward compatibility.

- **GPS L2C.** Defined at **Interface Specification IS-GPS-200 Revision M**, is only available on Block IIR-M and subsequent satellite blocks. Centered at $f_{\text{GPS L2}} = 1227.60$ MHz, the signal structure is the same than in (eq:GPSL1}), with the precision code in the In-phase component, just as in (eq:L1CAI}) but with an optional presence of the navigation message D_{NAV} . For the Quadrature-phase component, three options are defined:

$$e_{L2CQ}(t) = \sum_{l=-\infty}^{\infty} D_{\text{CNAV}}[l]_{10230} \oplus \left(C_{\text{CL}}[l]_{L_{\text{CL}}} p_{1/2}(t - lT_{c,L2C}) + \right. \quad (3.6)$$

$$\left. + C_{\text{CM}}[l]_{L_{\text{CM}}} p_{1/2}\left(t - \left(l + \frac{3}{4}\right) T_{c,L2C}\right) \right), \quad (3.7)$$

$$e_{L2CQ}(t) = \sum_{l=-\infty}^{\infty} D_{\text{NAV}}[l]_{20460} \oplus C_{\text{C/A}}[l]_{1023} p(t - lT_{c,C/A}), \text{ or} \quad (3.8)$$

$$e_{L2CQ}(t) = \sum_{l=-\infty}^{\infty} C_{\text{C/A}}[l]_{1023} p(t - lT_{c,C/A}), \quad (3.9)$$

where $T_{c,L2C} = \frac{1}{511.5}$ ms and $p_{1/2}(t)$ is a rectangular pulse of half chip-period duration, thus time-multiplexing both codes. The civilian long code C_{CL} is $L_{\text{CL}} = 767250$ chips long, repeating every 1.5 s, while the civilian moderate code C_{CM} is $L_{\text{CL}} = 10230$ chips long and its repeats every 20 ms. The CNAV data is an upgraded version of the original NAV navigation message, containing higher precision representation and nominally more accurate data than the NAV data. It is transmitted at 25 bps with forward error correction (FEC) encoding, resulting in 50 sps.

- **GPS L5.** The GPS L5 link, defined at **Interface Specification IS-GPS-705 Revision H**, is only available in Block IIF (first satellite launched on May, 2010) and subsequent satellite blocks. Centered at $f_{\text{GPS L5}} = 1176.45$ MHz, this signal in space can be written as:

$$s_T^{(\text{GPS L5})}(t) = e_{L5I}(t) + je_{L5Q}(t), \quad (3.10)$$

$$e_{L5I}(t) = \sum_{m=-\infty}^{+\infty} C_{nh10}[m]_{10} \oplus D_{\text{CNAV}}[m]_{10} \oplus \sum_{l=1}^{102300} C_{L5I}[l]_{10230} p(t - mT_{c,nh} - lT_{c,L5}), \quad (3.11)$$

$$e_{L5Q}(t) = \sum_{m=-\infty}^{+\infty} C_{nh20}[m]_{20} \oplus \sum_{l=1}^{102300} C_{L5Q}[l]_{10230} \cdot p(t - mT_{c,nh} - lT_{c,L5}), \quad (3.12)$$

where $T_{c,nh} = 1$ ms and $T_{c,L5} = \frac{1}{10.23}$ μ s, thus defining a BPSK(10) modulation. Both L5I and L5Q contain synchronization sequences.

3.1.2 GLONASS signal in space

The nominal baseline constellation of the Russian Federation's Global Navigation Satellite System (GLONASS) comprises 24 GLONASS-M satellites that are uniformly deployed in three roughly circular orbital planes at an inclination of 64.8° to the equator. The altitude of the orbit is 19,100 km. The orbit period of each satellite is 11 hours, 15 minutes, and 45 seconds. The orbital planes are separated by 120° right ascension of the ascending node. Eight satellites are equally spaced in each plane with 45° argument of latitude. Moreover, the orbital planes have an argument of latitude displacement of 15° relative to each other.

GLONASS civil signal-in-space is defined at **Interface Control Document. Navigational radiosignal in bands L1, L2. Edition 5.1**. This system makes use of a frequency-division multiple access (FDMA) signal structure, transmitting in two bands: $f_{\text{GLOL1}}^{(k)} = 1602 + k \cdot 0.5625$ MHz and $f_{\text{GLOL2}}^{(k)} = 1246 + k \cdot 0.4375$ MHz, where $k \in \{-7, -6, \dots, 5, 6\}$ is the channel number. Satellites in opposite points of an orbit plane transmit signals on equal frequencies, as these satellites will never be in view simultaneously by a ground-based user.

- **GLONASS L1.** Two kind of signals are transmitted: a standard precision (SP) and an obfuscated high precision (HP) signal. The complex baseband transmitted signal can be written as

$$s_T^{(\text{GLO L1})}(t) = e_{L1I}(t) + je_{L1Q}(t), \quad (3.13)$$

with BPSK(5) and BPSK(0.5) modulations:

$$e_{L1I}(t) = \sum_{l=-\infty}^{\infty} D_{\text{GNAV}}[l]_{102200} \oplus C_{\text{HP}}[l]_{L_{\text{HP}}} p(t - lT_{c,\text{HP}}), \quad (3.14)$$

$$e_{L1Q}(t) = \sum_{l=-\infty}^{\infty} D_{\text{GNAV}}[l]_{10220} \oplus C_{\text{SP}}[l]_{511} p(t - lT_{c,\text{SP}}), \quad (3.15)$$

where $T_{c,\text{HP}} = \frac{1}{5.11} \mu\text{s}$, $T_{c,\text{SP}} = \frac{1}{0.511} \mu\text{s}$, and $L_{\text{HP}} = 3.3554 \cdot 10^7$. The navigation message D_{GNAV} is transmitted at 50 bps. Details of its content and structure, as well as the generation of the C_{SP} code, can be found at the [ICD](#). The usage of the HP signal should be agreed with the Russian Federation Defense Ministry, and no more details have been disclosed.

- **GLONASS L2.** Beginning with the second generation of satellites, called GLONASS-M and first launched in 2001, a second civil signal is available using the same SP code than the one in the L1 band.

The use of FDMA techniques, in which the same code is used to broadcast navigation signals on different frequencies, and the placement of civil GLONASS transmissions on frequencies close to 1600 MHz, well above the GPS L1 band, have complicated the design of combined GLONASS/GPS receivers, particularly low-cost equipment for mass-market applications. Future plans of modernization are intended to increase compatibility and interoperability with other GNSS, and include the addition of a code-division multiple access (CDMA) structure, and possibly binary offset carrier (BOC) modulation, beginning with the third civil signal in the L3 band (1197.648 – 1212.255 MHz). Russia is implementing the new signals on the next-generation GLONASS-K satellites, with a first prototype successfully launched into orbit on February 26, 2011.

3.1.3 Galileo signal in space

The nominal Galileo constellation comprises a total of 27 operational satellites (plus 3 active spares), that are evenly distributed among three orbital planes inclined at 56° relative to the equator. There are nine operational satellites per orbital plane, occupying evenly distributed orbital slots. Three additional spare satellites (one per orbital plane) complement the nominal constellation configuration. The Galileo satellites are placed in quasi-circular Earth orbits with a nominal semi-major axis of about 30,000 km and an approximate revolution period of 14 hours. The Control segment full infrastructure will be composed of 30 – 40 sensor stations, 3 control centers, 9 Mission Uplink stations, and 5 TT&C stations.

Galileo's Open Service is defined at [Signal In Space Interface Control Document](#). [Ref: OS SIS ICD, Issue 2.0](#), where the following signal structures are specified:

- **Galileo E1.** This band, centered at $f_{\text{Gal E1}} = 1575.420$ MHz and with a reference bandwidth of 24.5520 MHz, uses the so-called composite binary offset carrier CBOC(6,1, $\frac{1}{11}$) modulation, defined in baseband as:

$$s_T^{(\text{Gal E1})}(t) = \frac{1}{\sqrt{2}} \left(e_{E1B}(t) (\alpha sc_A(t) + \beta sc_B(t)) + \right. \quad (3.16)$$

$$\left. - e_{E1C}(t) (\alpha sc_A(t) - \beta sc_B(t)) \right), \quad (3.17)$$

where the subcarriers $sc(t)$ are defined as

$$sc_A(t) = \text{sign}(\sin(2\pi f_{s,E1A}t)), \quad (3.18)$$

$$sc_B(t) = \text{sign}(\sin(2\pi f_{s,E1B}t)), \quad (3.19)$$

and $f_{s,E1A} = 1.023$ MHz, $f_{s,E1B} = 6.138$ MHz are the subcarrier rates, $\alpha = \sqrt{\frac{10}{11}}$, and $\beta = \sqrt{\frac{1}{11}}$. Channel B contains the I/NAV type of navigation message, $D_{I/NAV}$, intended for Safety-of-Life (SoL) services:

$$e_{E1B}(t) = \sum_{l=-\infty}^{+\infty} D_{I/NAV} \left[[l]_{4092} \right] \oplus C_{E1B} \left[[l]_{4092} \right] p(t - lT_{c,E1B}). \quad (3.20)$$

In case of channel C, it is a pilot (dataless) channel with a secondary code, forming a tiered code:

$$e_{E1C}(t) = \sum_{m=-\infty}^{+\infty} C_{E1Cs} \left[[m]_{25} \right] \oplus \sum_{l=1}^{4092} C_{E1Cp} \left[[l] \right] \cdot p(t - mT_{c,E1Cs} - lT_{c,E1Cp}), \quad (3.21)$$

with $T_{c,E1B} = T_{c,E1Cp} = \frac{1}{1.023} \mu\text{s}$ and $T_{c,E1Cs} = 4$ ms. The C_{E1B} and C_{E1Cp} primary codes are pseudorandom memory code sequences defined at Annex C of OS SIS ICD. The binary sequence of the secondary code C_{E1Cs} is 0011100000001010110110010. This band also contains another component, Galileo E1A, intended for the Public Regulated Service (PRS). It uses a BOC(15,2.5) modulation with cosine-shaped subcarrier $f_{s,E1A} = 15.345$ MHz and $T_{c,E1A} = \frac{1}{2.5575} \mu\text{s}$. The PRS spreading codes and the structure of the navigation message have not been made public.

- **Galileo E6.** Intended for the Commercial Service and centered at $f_{\text{Gal E6}} = 1278.750$ MHz, this band provides pilot and data components

$$s_T^{(\text{Gal E6})}(t) = \frac{1}{\sqrt{2}} (e_{E6B}(t) - e_{E6C}(t)), \quad (3.22)$$

$$e_{E6B}(t) = \sum_{m=-\infty}^{+\infty} D_{C/NAV} \left[[l]_{5115} \right] \oplus C_{E6B} \left[[l]_{L_{E6B}} \right] \cdot p(t - lT_{c,E6}), \quad (3.23)$$

$$e_{E6C}(t) = \sum_{m=-\infty}^{+\infty} C_{E6Cs} \left[[m]_{100} \right] \oplus \sum_{l=1}^{L_{E6C}} C_{E6Cp} \left[[l] \right] \cdot p(t - mT_{c,E6s} - lT_{c,E6p}), \quad (3.24)$$

where $D_{C/NAV}$ is the C/NAV navigation data stream, which is modulated with the encrypted ranging code C_{E6B} with chip period $T_{c,E6} = \frac{1}{5.115} \mu\text{s}$, thus being a BPSK(5) modulation. Codes C_{E6B} and primary codes C_{E6Cs} and their respective lengths, L_{E6B} and L_{E6C} , have not been published. The secondary codes for the pilot component, C_{E6Cp} , are available at the OS SIS ICD. The receiver reference bandwidth for this signal is 40.920 MHz. This band also contains another component, Galileo E6A, intended for PRS.

- **Galileo E5.** Centered at $f_{\text{Gal E5}} = 1191.795$ MHz and with a total bandwidth of 51.150 MHz, its signal structure deserves some analysis. The AltBOC modulation can be generically expressed as

$$s^{\text{AltBOC}}(t) = x_1(t)v^*(t) + x_2(t)v(t), \quad (3.25)$$

where $v(t) = \frac{1}{\sqrt{2}} (\text{sign}(\cos(2\pi f_s t)) + j \text{sign}(\sin(2\pi f_s t)))$ is the single side-band subcarrier, f_s is the subcarrier frequency, $(\cdot)^*$ stands for the conjugate operation, and $x_1(t)$ and $x_2(t)$ are QPSK signals. The resulting waveform does not exhibit constant envelope. In case of Galileo, the need for high efficiency of the satellites' onboard High Power Amplifier (HPA) has pushed a modification on the signal in order to make it envelope-constant and thus use the HPA at saturation. This can be done by adding some inter-modulation products to the expression above, coming up with the following definition:

$$s_T^{(\text{Gal E5})}(t) = e_{E5a}(t)ssc_s^*(t) + e_{E5b}(t)ssc_s(t) + \bar{e}_{E5a}(t)ssc_p^*(t) + \bar{e}_{E5b}(t)ssc_p(t), \quad (3.26)$$

where the single and product side-band signal subcarriers are

$$ssc_s(t) = sc_s(t) + jsc_s\left(t - \frac{T_s}{4}\right), \quad (3.27)$$

$$ssc_p(t) = sc_p(t) + jsc_p\left(t - \frac{T_s}{4}\right), \quad (3.28)$$

and

$$e_{E5a}(t) = e_{E5aI}(t) + je_{E5aQ}(t), \quad (3.29)$$

$$e_{E5b}(t) = e_{E5bI}(t) + je_{E5bQ}(t), \quad (3.30)$$

$$\bar{e}_{E5a}(t) = \bar{e}_{E5aI}(t) + j\bar{e}_{E5aQ}(t), \quad (3.31)$$

$$\bar{e}_{E5b}(t) = \bar{e}_{E5bI}(t) + j\bar{e}_{E5bQ}(t), \quad (3.32)$$

$$\bar{e}_{E5aI}(t) = e_{E5aQ}(t)e_{E5bI}(t)e_{E5bQ}(t), \quad (3.33)$$

$$\bar{e}_{E5aQ}(t) = e_{E5aI}(t)e_{E5bI}(t)e_{E5bQ}(t), \quad (3.34)$$

$$\bar{e}_{E5bI}(t) = e_{E5bQ}(t)e_{E5aI}(t)e_{E5aQ}(t), \quad (3.35)$$

$$\bar{e}_{E5bQ}(t) = e_{E5bI}(t)e_{E5aI}(t)e_{E5aQ}(t). \quad (3.36)$$

The signal components are defined as

$$e_{E5aI}(t) = \sum_{m=-\infty}^{+\infty} C_{E5aIs} \left[|m|_{20} \right] \oplus \sum_{l=1}^{10230} C_{E5aIp} \left[l \right] \oplus \quad (3.37)$$

$$\oplus D_{F/NAV} \left[[l]_{204600} \right] p(t - mT_{c,E5s} - lT_{c,E5p}), \quad (3.38)$$

$$e_{E5aQ}(t) = \sum_{m=-\infty}^{+\infty} C_{E5aQs} \left[|m|_{100} \right] \oplus \sum_{l=1}^{10230} C_{E5aQp} \left[l \right] \cdot \quad (3.39)$$

$$\cdot p(t - mT_{c,E5s} - lT_{c,E5p}), \quad (3.40)$$

$$e_{E5bI}(t) = \sum_{m=-\infty}^{+\infty} C_{E5bIs} \left[|m|_4 \right] \oplus \sum_{l=1}^{10230} C_{E5bIp} \left[l \right] \oplus \quad (3.41)$$

$$\oplus D_{I/NAV} \left[[l]_{40920} \right] p(t - mT_{c,E5s} - lT_{c,E5p}), \quad (3.42)$$

$$e_{E5bQ}(t) = \sum_{m=-\infty}^{+\infty} C_{E5bQs} \left[|m|_{100} \right] \oplus \sum_{l=1}^{10230} C_{E5bQp} \left[l \right] \cdot \quad (3.43)$$

$$\cdot p(t - mT_{c,E5s} - lT_{c,E5p}), \quad (3.44)$$

where $T_{c,E5s} = 1$ ms and $T_{c,E5p} = \frac{1}{10.23} \mu\text{s}$. **Channel A** contains the F/NAV type of navigation message, $D_{F/NAV}$, intended for the Open Service. The I/NAV message structures for the E5bI and E1B signals use the same page layout. Only page sequencing is different, with page swapping between both components in order to allow a fast reception of data by a dual frequency receiver. The single subcarrier $sc_s(t)$ and the product subcarrier $sc_p(t)$ are defined as:

$$sc_s(t) = \frac{\sqrt{2}}{4} \text{sign} \left(\cos \left(2\pi f_s t - \frac{\pi}{4} \right) \right) + \quad (3.45)$$

$$+ \frac{1}{2} \text{sign} \left(\cos (2\pi f_s t) \right) + \frac{\sqrt{2}}{4} \text{sign} \left(\cos \left(2\pi f_s t + \frac{\pi}{4} \right) \right), \quad (3.46)$$

$$sc_p(t) = -\frac{\sqrt{2}}{4} \text{sign} \left(\cos \left(2\pi f_s t - \frac{\pi}{4} \right) \right) + \quad (3.47)$$

$$+ \frac{1}{2} \text{sign} \left(\cos (2\pi f_s t) \right) - \frac{\sqrt{2}}{4} \text{sign} \left(\cos \left(2\pi f_s t + \frac{\pi}{4} \right) \right), \quad (3.48)$$

with a subcarrier frequency of $f_s = 15.345$ MHz, thus defining an AltBOC(15,10) modulation. The QPSK(10) signal $e_{E5a}(t)$ defined above is shifted to $f_{\text{Gal E5a}} \doteq f_{\text{Gal E5}} - f_s = 1176.450$ MHz, while $e_{E5b}(t)$ is shifted to $f_{\text{Gal E5b}} \doteq f_{\text{Gal E5}} + f_s = 1207.140$ MHz. Thus, we can bandpass filter around $f_{\text{Gal E5a}}$ and get a good approximation of a QPSK(10) signal, with very low energy components of $e_{E5b}(t)$, $\bar{e}_{E5a}(t)$, and $\bar{e}_{E5b}(t)$:

$$s_T^{(\text{Gal E5a})}(t) \simeq e_{E5aI}(t) + je_{E5aQ}(t). \quad (3.49)$$

The same applies to $e_{E5b}(t)$, allowing an independent reception of two QPSK(10) signals and thus requiring considerably less bandwidth than the processing of the whole E5 band.

This header file contains the interface to an abstract class for signal sources. Since all its methods are virtual, this class cannot be instantiated directly, and a subclass can only be instantiated directly if all inherited pure virtual methods have been implemented by that class or a parent class.

10.2.3.4 Function Documentation

10.2.3.4.1 find_uio_dev_file_name()

```
int32_t find_uio_dev_file_name (
    std::string & device_file_name,
    const std::string & device_name,
    uint32_t device_num)
```

This function finds the uio device driver device file name out of the device name and the device number.

10.2.3.4.2 get_num_devices()

```
uint32_t get_num_devices (
    const std::string & device_name)
```

Returns the number of devices (tracking multicorrelators) of type device_name available in the FPGA.

10.2.3.4.3 ini_parse()

```
int ini_parse (
    const char * filename,
    int(* handler ) (void *user, const char *section, const char *name, const char
    *value),
    void * user)
```

Parse given INI-style file. May have [section]s, name=value pairs (whitespace stripped), and comments starting with ';' (semicolon). Section is "" if name=value pair parsed before any section heading.

For each name=value pair parsed, call handler function with given user pointer as well as section, name, and value (data only valid for duration of handler call). Handler should return nonzero on success, zero on error.

Returns 0 on success, line number of first error on parse error, on -1 on file open error.

The Carrier Phase Lock Detector block uses the estimate of the cosine of twice the carrier phase error is given by

$$C2\phi = \frac{NBD}{NBP}, \quad (10.1)$$

where $NBD = (\sum_{i=0}^{N-1} |Im(Pc(i))|)^2 + (\sum_{i=0}^{N-1} |Re(Pc(i))|)^2$, $NBP = \sum_{i=0}^{N-1} Im(Pc(i))^2 - \sum_{i=0}^{N-1} Re(Pc(i))^2$, and $Pc(i)$ is the prompt correlator output for the sample index i . 10.13.4.4.4 cn0_m2m4_estimator()

```
float cn0_m2m4_estimator (
    const gr_complex * Prompt_buffer,
    int length,
    float coh_integration_time_s)
```

cn0_m2m4_estimator is a Carrier-to-Noise (CN0) estimator based on the Second- and Fourth-Order Moments Method (M2M4)

Signal-to-Noise (SNR) (ρ) estimator using the Moments Method:

$$\hat{\rho} = \frac{\sqrt{2\hat{M}_2^2 - \hat{M}_4}}{\hat{M}_2 - \sqrt{2\hat{M}_2^2 - \hat{M}_4}}, \quad (10.2)$$

where $\hat{M}_2 = \frac{1}{N} \sum_{k=0}^{K-1} |P[k]|^2$, $\hat{M}_4 = \frac{1}{K} \sum_{k=0}^{K-1} |P[k]|^4$, $|\cdot|$ is the absolute value, and $P[k]$ is the prompt correlator output for the sample index k .

The SNR value is converted to CN0 [dB-Hz] taking into account the coherent integration time, using the following formula:

$$CN0_{dB} = 10 * \log(\hat{\rho}) - 10 * \log(T_{int}), \quad (10.3)$$

where T_{int} is the coherent integration time, in seconds.

10.13.4.4.5 cn0_svn_estimator()

```
float cn0_svn_estimator (
    const gr_complex * Prompt_buffer,
    int length,
    float coh_integration_time_s)
```

`cn0_svn_estimator` is a Carrier-to-Noise (CN0) estimator based on the Signal-to-Noise Variance (SNV) estimator Signal-to-Noise (SNR) (ρ) estimator using the Signal-to-Noise Variance (SNV) estimator:

$$\hat{\rho} = \frac{\hat{P}_s}{\hat{P}_n} = \frac{\hat{P}_s}{\hat{P}_{tot} - \hat{P}_s}, \quad (10.4)$$

where $\hat{P}_s = \left(\frac{1}{N} \sum_{i=0}^{N-1} |Re(Pc(i))| \right)^2$ is the estimation of the signal power, $\hat{P}_{tot} = \frac{1}{N} \sum_{i=0}^{N-1} |Pc(i)|^2$ is the estimator of the total power, $|\cdot|$ is the absolute value, $Re(\cdot)$ stands for the real part of the value, and $Pc(i)$ is the prompt correlator output for the sample index i .

The SNR value is converted to CN0 [dB-Hz], taking into account the coherent integration time, using the following formula:

$$CN0_{dB} = 10 * \log(\hat{\rho}) - 10 * \log(T_{int}), \quad (10.5)$$

where T_{int} is the coherent integration time, in seconds.

12.23.1 Detailed Description

[Bayesian_estimator](#) is an estimator of noise characteristics (i.e. mean, covariance).

[Bayesian_estimator](#) is an estimator which performs estimation of noise characteristics from a sequence of identically and independently distributed (IID) samples of a stationary stochastic process by way of Bayesian inference using conjugate priors. The posterior distribution is assumed to be Gaussian with mean $\mathbf{\mu}$ and covariance $\hat{\mathbf{C}}$, which has a conjugate prior given by a normal-inverse-Wishart distribution with parameters $\mathbf{\mu}_0$, $\mathbf{\kappa}_0$, $\mathbf{\nu}_0$, and $\mathbf{\Psi}$.

12.59 HistogramBitSynchronizer::Config Struct Reference

Configuration parameters for [HistogramBitSynchronizer](#).

```
#include <bit_synchronizer.h>
```

Public Attributes

- int [bit_period_ms](#)
Navigation data bit period in milliseconds.
- int [epoch_ms](#)
Time interval between successive calls to [update\(\)](#), in milliseconds.
- int [min_events_for_lock](#)
Minimum number of detected transition events required before lock evaluation.
- double [dominance_ratio](#)
Required dominance ratio of the winning histogram bin.
- int [stable_best_required](#)
Required stability of the dominant histogram bin (consecutive evaluations).
- float [min_prompt_mag](#)

Minimum magnitude of the prompt correlator output.

- bool [use_phase_dot_detector](#)

Select the transition detection method.

12.59.1 Detailed Description

Configuration parameters for [HistogramBitSynchronizer](#).

These parameters define the bit period, the update cadence, the lock criteria, and the transition detection method. Definition at line 43 of file [bit_synchronizer.h](#).

12.59.2 Constructor & Destructor Documentation

12.59.2.1 Config()

```
HistogramBitSynchronizer::Config::Config () [inline]
```

Definition at line 128 of file [bit_synchronizer.h](#).

12.59.3 Member Data Documentation

12.59.3.1 bit_period_ms

```
int HistogramBitSynchronizer::Config::bit_period_ms
```

Navigation data bit period in milliseconds.

This is the nominal duration of one navigation data bit.

Definition at line 50 of file [bit_synchronizer.h](#).

12.59.3.2 dominance_ratio

```
double HistogramBitSynchronizer::Config::dominance_ratio
```

Required dominance ratio of the winning histogram bin.

Lock requires the most frequent histogram bin to be sufficiently dominant:

$$\text{dominance_ratio} = \frac{\text{best_bin_count}}{\text{total_detected_events}}$$

Guidance:

- Values near 0.5 may lock faster but increase false-lock probability.
- Values closer to 1.0 are conservative and require a clearly dominant phase.

Definition at line 84 of file [bit_synchronizer.h](#).

12.59.3.3 epoch_ms

```
int HistogramBitSynchronizer::Config::epoch_ms
```

Time interval between successive calls to [update\(\)](#), in milliseconds.

This should match the minimum integration interval (epoch) produced by the tracking loop and used to generate the provided prompt correlator output.

Definition at line 58 of file [bit_synchronizer.h](#).

12.59.3.4 min_events_for_lock

```
int HistogramBitSynchronizer::Config::min_events_for_lock
```

Minimum number of detected transition events required before lock evaluation.

The histogram is built from detected candidate transitions. Lock decisions are not attempted until at least this many events have been accumulated.

Trade-offs:

- Larger values increase robustness against false locks but increase time-to-lock.
- Smaller values reduce time-to-lock but increase sensitivity to noise/spurious transitions.

Definition at line 70 of file [bit_synchronizer.h](#).

12.59.3.5 min_prompt_mag

```
float HistogramBitSynchronizer::Config::min_prompt_mag
```

Minimum magnitude of the prompt correlator output.

Candidate transition detection is suppressed when $|P| < \text{min_prompt_mag}$, where P is the prompt correlator output.

Use this to avoid counting unreliable transitions when tracking quality is poor or the prompt output is dominated by noise.

Definition at line 105 of file [bit_synchronizer.h](#).

12.59.3.6 stable_best_required

```
int HistogramBitSynchronizer::Config::stable_best_required
```

Required stability of the dominant histogram bin (consecutive evaluations).

Even if the dominance ratio is met, the algorithm requires that the same histogram bin remains dominant for this many consecutive lock evaluations before declaring lock.

This helps prevent locking on transient peaks caused by noise or short-lived disturbances.

Definition at line 94 of file [bit_synchronizer.h](#).

12.59.3.7 use_phase_dot_detector

```
bool HistogramBitSynchronizer::Config::use_phase_dot_detector
```

Select the transition detection method.

If true (recommended), uses a “phase-dot” detector:

- A candidate transition is detected when:

$$\Re\{P_k \cdot P_{k-1}^*\} < 0$$

where P_k is the current prompt and P_{k-1}^* the conjugate of the previous.

This method is largely insensitive to constant carrier phase rotations and is often more robust during early tracking / imperfect carrier phase alignment.

If false, uses a simpler sign-change detector on the real part:

- A candidate transition is detected when $\text{sign}(\text{Re}(P_k)) \neq \text{sign}(\text{Re}(P_{k-1}))$.

This assumes the prompt output is already aligned with the data bit polarity (i.e., stable PLL lock and correct navigation bit polarity mapping).

12.60.1 Detailed Description

This abstract class represents an interface to configuration parameters.

The interface defines an accessor method that gets a parameter name as input and returns the value of this parameter, a string, as output. Property names are defined here. This is an abstract class for interfaces. Since all its methods are virtual, this class cannot be instantiated directly, and a subclass can only be instantiated directly if all inherited pure virtual methods have been implemented by that class or a parent class.

.sample_type - data type read out from the FIFO. default is short ;

- note: not output format. that is always gr_complex

.dump - whether to archive input data

.dump_filename - if dumping, path to file for output

12.98.1 Detailed Description

This class is an implementation of the interface [ConfigurationInterface](#).

Derived from [ConfigurationInterface](#), this class implements an interface to a configuration file. This implementation has a text file as the source for the values of the parameters. The file is in the INI format, containing sections and pairs of names and values. For more information about the INI format, see https://en.wikipedia.org/wiki/INI_file

12.100.1 Detailed Description

Base class to file-oriented [SignalSourceBase](#) GNSS blocks.

This class supports the following properties:

.filename - the path to the input file

- may be overridden by the -signal_source or -s command-line arguments

.samples - number of samples to process (default 0)

- if not specified or 0, read the entire file; otherwise stop after that many samples

.sampling_frequency - the frequency of the sampled data (samples/second)

.item_type - data type of the samples (default "short")

.header_size - the size of a prefixed header to skip in "samples" (default 0)

.seconds_to_skip - number of seconds of lead-in data to skip over (default 0)

.enable_throttle_control - whether to stop reading if the upstream buffer is full (default false)

.repeat - whether to rewind and continue at end of file (default false)

(probably abstracted to the base class)

.dump - whether to archive input data

.dump_filename - if dumping, path to file for output

The purpose of this is to have the option to allow the FPGA to compensate for a possible deviation between the nominal value of the PRN code length and the measured PRN code length in the PRN immediately following the start of the coherent integration only. This class adapts a gnuradio gr_freq_xlating_fir_filter designed with pm_remez.

Construct a FIR filter with the given taps and a composite frequency translation that shifts intermediate_freq_down to zero Hz. The frequency translation logically comes before the filtering operation.

See Parks-McClellan FIR filter design, https://en.wikipedia.org/wiki/Parks-McClellan_filter_design_algorithm Calculates the optimal (in the Chebyshev/minimax sense) FIR filter impulse response given a set of band edges, the desired response on those bands, and the weight given to the error in those bands.

12.162.3.1 compute_GLONASS_time()

```
boost::posix_time::ptime Glonass_Gnav_Ephemeris::compute_GLONASS_time (
    double offset_time) const
```

Computes the GLONASS System Time and returns a boost::posix_time::ptime object \ param offset_time Is the start of day offset to compute the time.

12.162.3.2 glot_to_gpst()

```
void Glonass_Gnav_Ephemeris::glot_to_gpst (
    double tod_offset,
    double glot2utc_corr,
    double glot2gpst_corr,
    int32_t * WN,
    double * TOW) const
```

Converts from GLONASST to GPST.

Converts from GLONASST to GPST in time of week (TOW) and week number (WN) format

Parameters

in	<i>tod_offset</i>	Is the start of day offset
in	<i>glot2utc_corr</i>	Correction from GLONASST to UTC
in	<i>glot2gpst_corr</i>	Correction from GLONASST to GPST
out	<i>WN</i>	Week Number, not in mod(1024) format
out	<i>TOW</i>	Time of Week in seconds of week

```
boost::posix_time::ptime Glonass_Gnav_Ephemeris::glot_to_utc (
    double offset_time,
    double glot2utc_corr) const
```

Converts from GLONASST to UTC.

The function simply adjust for the 6 hrs offset between GLONASST and UTC

Parameters

in	<i>offset_time</i>	Is the start of day offset
in	<i>glot2utc_corr</i>	Correction from GLONASST to UTC

Returns

UTC time as a boost::posix_time::ptime object

12.244.1 Detailed Description

Histogram-based navigation data bit synchronizer.

Definition at line 34 of file [bit_synchronizer.h](#).

12.244.2 Constructor & Destructor Documentation

12.244.2.1 HistogramBitSynchronizer()

```
HistogramBitSynchronizer::HistogramBitSynchronizer (
    const Config & cfg) [inline], [explicit]
```

Construct a histogram bit synchronizer with the provided configuration.

Initializes internal counters and allocates the histogram with [bins\(\)](#) entries, all set to zero.

Parameters

<i>cfg</i>	Configuration parameters.
------------	---------------------------

Definition at line 148 of file [bit_synchronizer.h](#).

References [bins\(\)](#).

12.244.3 Member Function Documentation

12.244.3.1 bins()

```
int HistogramBitSynchronizer::bins () const
```

Return the number of histogram bins.

Derived from the bit period and epoch duration, e.g.: $\text{bins} = \text{bit_period_ms} / \text{epoch_ms}$

Returns

Number of histogram bins.

Referenced by [HistogramBitSynchronizer\(\)](#).

12.244.3.2 edge_phase()

```
int HistogramBitSynchronizer::edge_phase () const [inline]
```

Get the estimated bit edge phase bin.

The edge phase is expressed as an integer histogram bin index in the range $[0, \text{bins}()-1]$ when locked. The interpretation is “which epoch phase within the bit period is most likely to contain a navigation bit transition.”

Returns

Estimated edge phase bin index, or -1 if not locked.

Definition at line 213 of file [bit_synchronizer.h](#).

12.244.3.3 epochs_until_next_edge()

```
int HistogramBitSynchronizer::epochs_until_next_edge () const
```

Return the number of epochs until the next predicted navigation bit edge.

When the synchronizer is locked, this function computes the forward distance (in epochs) from the most recently processed epoch to the next epoch that is aligned with the estimated bit-edge phase.

The result is expressed modulo the bit period and has the following meaning:

- 0 : the current epoch corresponds to the predicted start of a new navigation bit
- >0 : number of epochs remaining until the next bit boundary

The computation is based on the internal epoch counter advanced by [update\(\)](#), assuming that [update\(\)](#) is called once per epoch with a constant cadence equal to [Config::epoch_ms](#).

If the synchronizer is not locked, or if the configuration yields an invalid number of bins, this function returns -1.

Returns

Number of epochs until the next predicted bit edge, or -1 if not locked or if the bit period configuration is invalid.

12.244.3.4 get_epoch_count()

```
std::int64_t HistogramBitSynchronizer::get_epoch_count () const [inline]
```

Total number of epochs processed by [update\(\)](#).

This counter increments once per call to [update\(\)](#), regardless of whether a transition is detected or whether `tracking_quality_ok` is true.

Returns

Total processed epochs.

Definition at line 264 of file [bit_synchronizer.h](#).

12.244.3.5 get_histogram()

```
const std::vector< int > & HistogramBitSynchronizer::get_histogram () const [inline]
```

Access the internal histogram (read-only).

Each entry counts how many detected candidate transitions occurred at the corresponding phase bin within the bit period.

Returns

Reference to the histogram vector.

Definition at line 247 of file [bit_synchronizer.h](#).

12.244.3.6 get_total_events()

```
std::int64_t HistogramBitSynchronizer::get_total_events () const [inline]
```

Total number of detected transition events accumulated into the histogram.

Returns

Total detected events.

Definition at line 254 of file [bit_synchronizer.h](#).

12.244.3.7 is_edge_epoch()

```
bool HistogramBitSynchronizer::is_edge_epoch (
    std::int64_t k) const
```

Predict whether a given epoch index corresponds to a bit edge.

For a given epoch index `k` (0-based), this function returns true when `k` is aligned with the currently estimated edge phase (i.e., the predicted transition epoch), and false otherwise.

If not locked, this always returns false.

Parameters

<code>k</code>	Epoch index (0-based, consistent with the caller's epoch counting).
----------------	---

Returns

True if `k` is the predicted edge epoch; false otherwise.

12.244.3.8 locked()

```
bool HistogramBitSynchronizer::locked () const [inline]
```

Query whether the synchronizer has achieved lock.

Returns

True if lock has been declared, false otherwise.

Definition at line 202 of file [bit_synchronizer.h](#).

12.244.3.9 reset()

```
void HistogramBitSynchronizer::reset ()
```

Reset the synchronizer state.

Clears the histogram and all internal counters/flags, returning the instance to the pre-lock state:

- [locked\(\)](#) becomes false
- [edge_phase\(\)](#) becomes -1
- `total_events` and `epoch_count` are reset to zero

12.244.3.10 update()

```
bool HistogramBitSynchronizer::update (
    const std::complex< float > & prompt,
    bool tracking_quality_ok)
```

Update the synchronizer once per epoch.

This method should be called at a fixed cadence defined by [Config::epoch_ms](#)

The method:

- Advances the internal epoch counter,
- Optionally performs candidate transition detection if tracking quality is acceptable,
- Updates the phase histogram on detected transitions,
- Evaluates lock once enough events have been gathered.

Parameters

<i>prompt</i>	Prompt correlator output for the current epoch.
<i>tracking_quality_ok</i>	Indicates whether tracking quality is sufficient to trust the prompt sample for transition detection (e.g., code/carrier lock metrics).

Returns

True only on the epoch when lock is first declared; false otherwise (including subsequent epochs after lock has been achieved).

12.351.1 Detailed Description

Class implementing a Reed-Solomon encoder and decoder RS(255,K,d) where $k=255-nroots$ is the information vector length and $d=nroots+1$ is the minimum Hamming distance, with symbols of 8 bits. It allows shortened RS codes.

12.351.2 Constructor & Destructor Documentation

12.351.2.1 ReedSolomon() [1/2]

```
ReedSolomon::ReedSolomon (
    const std::string & gnss_signal = std::string()) [explicit]
```

Default constructor. Constructs a Reed Solomon object. The `encode_with_generator_poly` and `encode_with_generator_matrix` methods are available for testing purposes.

`gnss_signal`: empty or "E6B" sets the Galileo E6B RS parameters. "E1B" sets the Galileo E1B (INAV) RS parameters.

12.351.2.2 ReedSolomon() [2/2]

```
ReedSolomon::ReedSolomon (
    int nroots,
    int minpoly,
    int prim,
    int fcr,
    int pad = 0,
    int shortening = 0,
    const std::vector< uint8_t > & genpoly_coeff = std::vector< uint8_t > {},
    const std::vector< std::vector< uint8_t > > & gen_matrix = std::vector< std::vector< uint8_t > > {})
```

Custom constructor for RS(255, 255-nroots, nroots+1). Parameters:

`nroots` - the number of roots in the RS code generator polynomial, which is the same as the number of parity symbols in a block.

`minpoly` - primitive polynomial.

`prim` - the primitive root of the generator polynomial.

`fcr` - first consecutive root of the Reed-Solomon generator polynomial.

`pad` - the number of pad symbols in a block. If not defined, it defaults to 0.

`shortening` - value of the shortening parameter. Defaults to 0. If different to 0, it defines a shortened RS encoder/decoder.

`genpoly_coeff` - a vector of (nroots+1) elements containing the generator polynomial coefficients. Only used for encoding. Defaults to empty. If defined, the `encode_with_generator_poly` method can be used.

`gen_matrix` - a (255-shortening)x(255-nroots-shortening) matrix containing the elements of the generator matrix. Only used for encoding. Defaults to empty. If defined, the `encode_with_generator_matrix` method can be used.

12.351.3 Member Function Documentation

12.351.3.1 decode()

```
int ReedSolomon::decode (
    std::vector< uint8_t > & data_to_decode,
    const std::vector< int > & erasure_positions = std::vector< int > {}) const
```

Decode an encoded block.

The decoded symbols are at the first 255-nroots-shortening elements of the `data_to_decode` vector.

The second parameter is optional, and contains a vector of erasure positions to be passed to the decoding algorithm. Defaults to empty.

Returns the number of corrected errors, or -1 if decoding failed.

12.351.3.2 encode_with_generator_matrix()

```
std::vector< uint8_t > ReedSolomon::encode_with_generator_matrix (
```

```
const std::vector< uint8_t > & data_to_encode) const
```

Encode data with the generator matrix (for testing purposes).

Returns the encoded vector. It is set to all zeros if the generator matrix is not defined.

12.351.3.3 encode_with_generator_poly()

```
std::vector< uint8_t > ReedSolomon::encode_with_generator_poly (
```

```
const std::vector< uint8_t > & data_to_encode) const
```

Encode data with the generator polynomial (for testing purposes).

Returns the encoded vector. It is set to all zeros if the generator polynomial is not defined.

12.353.1 Detailed Description

This class implements the generation and reading of some Message Types defined in the RTCM 3.2 Standard, plus some utilities to handle messages.

Generation of the following Message Types: 1001, 1002, 1003, 1004, 1005, 1006, 1008, 1019, 1020, 1029, 1045

Decoding of the following Message Types: 1019, 1045

Generation of the following Multiple Signal Messages: MSM1 (message types 1071, 1091) MSM2 (message types 1072, 1092) MSM3 (message types 1073, 1093) MSM4 (message types 1074, 1094) MSM5 (message types 1075, 1095) MSM6 (message types 1076, 1096) MSM7 (message types 1077, 1097)

RTCM 3 message format (size in bits): +-----+-----+-----+-----+-----+ | preamble | 000000
| length | data message | parity | +-----+-----+-----+-----+-----+ | <- 8 ---> | <- 6 --> | <- 10
---> | <- length x 8 ---> | <- 24 --> | +-----+-----+-----+-----+-----+ |
